

# Machine Learning Engineer Assessment(RDCX)

As part of the machine learning assessment, I have built a **Machine Learning Model** which will predict **House Price** based on various features and deployed the model to **Heroku**. Heroku is a platform as a service (PaaS) that enables developers to build, run, and operate applications entirely in the cloud. So, whenever users will key in the attributes of different features, the App will give you the price estimations.

### House Price Prediction

**Attribute Information (in order):**

1. **Crime\_rate** : Per capita crime rate by area
2. **Zone** : Proportion of residential land zoned for lots over 25,000 sq.ft.
3. **Industry** : Proportion of non-retail business acres per town
4. **CHAS\_variable** : Charles River dummy variable (= 1 if tract bounds river; 0 otherwise)
5. **Nitric\_oxides** : Nitric oxides concentration (parts per 10 million)
6. **Number\_of\_rooms** : Average number of rooms per dwelling
7. **Property\_age** : Proportion of owner-occupied units built prior to 1940
8. **Distance** : Weighted distances to five employment centres
9. **Radial\_highways** : Index of accessibility to radial highways
10. **Property\_tax** : Full-value property-tax rate per \$10,000
11. **PT\_ratio** : Pupil-teacher ratio by town
12. **BK** :  $1000(Bk - 0.63)^2$  where Bk is the proportion of blacks by town
13. **L\_status** : % of lower status of the population

## Datasets:

I have taken the Boston House Pricing dataset which we can import from Skelarn. The dataset has 506 number of instances and 14 attribute information. This dataset was taken from the StatLib library which is maintained at Carnegie Mellon University.

**Libraries Used:** Pandas, Numpy, Matplotlib, Pickle, Seaborn, json, Flask.

**Tools Used:** Google Colab, Visual Studio Code, Postman, Docker, Heroku

**Language Used:** Python and HTML

## Methodology:

### 1. Data Pre-processing:

i) As a crucial part of data preprocessing, I have tried to find the null values using `isnull()` function, there are no null values in the dataset, I have also seen the outliers but they look proper for modeling. Using `describe ()` and `info ()` function, I have checked the description of different columns for the data and data type.

### 2. Exploratory Data Analysis (EDA):

i) Firstly, using `Seaborn.pairplot`, I have drawn a diagram to understand correlation between various column of the dataset, it is important because I need to see which columns are necessary for my target value, here in this dataset, the 'Price' is the target value. I have found some of the attributes are positively and negatively correlated with my target value.

ii) To understand more, I have drawn some scatter plots with our target data to understand the correlation methods.

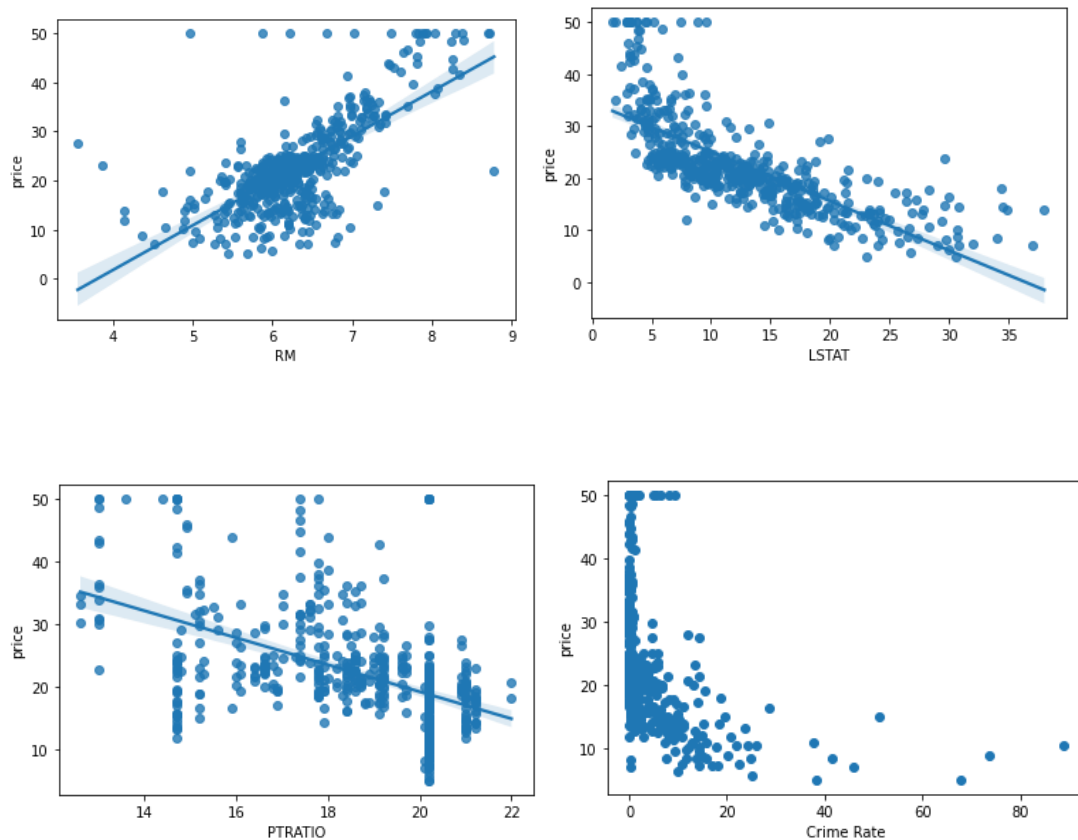

Fig 2: Understanding the Correlation

### 3. Creating our Models

i) Before creating a model, I have separated the dataset into train and test splits using `sklearn.model_selection`.

ii) Next, I have standardized my data using `StandScalar` from `Sklearn`, Data standardization helps improve the quality of your data by transforming and standardizing it. Standardization is an important technique that is mostly performed as a pre-processing step before many machine learning models, to standardize the range of features of an input data set.

iii) After completing all the techniques of data preprocessing and preparing the data for modeling, I have proceeded to the training phase. As it's Linear regression data, I have used the Linear Regression algorithm to train my model. I can use several other algorithms and choose the best one, but because this assessment is a time bound assessment and Linear Regression usually performs well with this sort of data, that's why I choose this algorithm. Linear regression analysis is used to predict the value of a variable based on the value of another variable. The variable you want to predict is called the dependent variable. The variable you are using to predict the other variable's value is called the independent variable.

See below the scatterplot which is predicted by my trained model.

Fig 3: scatter plot for the prediction

#### 4. Accuracy Measurement:

i) As part of the accuracy measurement, I have used 3 parameters which are mean absolute error, mean squared error and R squared and adjusted R square.

Mean Absolute error	3.744
Mean squared error	24.134
R squared	4.91

Finally, after getting the results from the model, I have pickled my model for further deployment.

#### Deployment:

For the deployment, I have created a Flask Rest API, with my trained model and then I have used Postman to test my API and finally I have created one Procfile and one Dockerfile to dockerize my model so that the infrastructure of the model remains same for every operating system, After finishing all of these steps, I have deployed my model to Heroku Cloud Platform, so the user can access the App.

##### 1. Flask API:

Flask is a popular micro framework for building web applications. Since it is a micro-framework, it is very easy to use and lacks most of the advanced functionality which is found in a full-fledged framework. Therefore, building a REST API in Flask is very simple.

##### 2. Postman:

Postman is an application used for API testing. It is an HTTP client that tests HTTP requests, utilizing a graphical user interface, through which we obtain different types of responses that need to be subsequently validated.

##### 3. Docker:

Docker is an open-source platform that enables developers to build, deploy, run, update and manage containers—standardized, executable components that combine application source code with the operating system (OS) libraries and dependencies required to run that code in any environment.

##### 4. Heroku

Heroku is a container-based cloud Platform as a Service (PaaS). Developers use Heroku to deploy, manage, and scale modern apps. Our platform is elegant, flexible, and easy to use, offering developers the simplest path to getting their apps to market.

## CI/CD Pipeline Using GitHub Actions:

As the whole project will be uploaded to GitHub that's why I have created a CI/CD pipeline (continuous integration/continuous delivery). This pipeline is very helpful because it will Ensure superior code quality, Deliver faster with an accelerated release rate, Continuous feedback and Optimum transparency and accountability.
